Creating Customer Segments

In this project you, will analyze a dataset containing annual spending amounts for internal structure, to understand the variation in the different types of customers that a wholesale distributor interacts with.

Instructions:

- Run each code block below by pressing Shift+Enter, making sure to implement any steps marked with a TODO.
- Answer each question in the space provided by editing the blocks labeled "Answer:".
- When you are done, submit the completed notebook (.ipynb) with all code blocks executed, as well as a .pdf version (File > Download as).

```
In [2]: # Import libraries: NumPy, pandas, matplotlib
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt

# Tell iPython to include plots inline in the notebook
%matplotlib inline

# Read dataset
data = pd.read_csv("wholesale-customers.csv")
print "Dataset has {} rows, {} columns".format(*data.shape)
print data.head() # print the first 5 rows
```

Dataset has 440 rows, 6 columns					
Fresh	Milk	Grocery	Frozen	Detergents_Paper	Delicatessen

Feature Transformation

1) In this section you will be using PCA and ICA to start to understand the structure of the data. Before doing any computations, what do you think will show up in your computations? List one or two ideas for what might show up as the first PCA dimensions, or what type of vectors will show up as ICA dimensions.

Answer: Principal component analysis (PCA) uses orthogonal transformation to decouple several correlated variables into a set of linearly uncorrelated variables. Also the first PCA variables has the largest possible variables. So the first PCA dimension must has "fresh" variables, whose variance is greatest among the six.

(Independent component analysis) ICA is used for separating a multivariate data into additive subcomponents. In this dataset, we would expected that all six variables to be included, since they seems not correlated to each other.

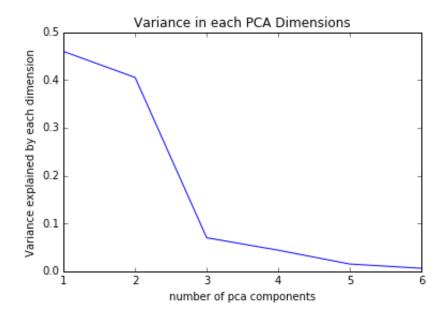

PCA

```
In [3]: # TODO: Apply PCA with the same number of dimensions as variables in the
    dataset
    from sklearn.decomposition import PCA
    pca = PCA(n_components = 6)
    pca.fit(data)
    # Print the components and the amount of variance in the data contained
    in each dimension
    print pca.components_
    print pca.explained_variance_ratio_

plt.figure()
    plt.plot(np.arange(1,7),pca.explained_variance_ratio_)
    plt.xlabel("number of pca components")
    plt.ylabel("Variance explained by each dimension")
    plt.title("Variance in each PCA Dimensions")
```

```

2) How quickly does the variance drop off by dimension? If you were to use PCA on this dataset, how many dimensions would you choose for your analysis? Why?

Answer: For the figure above, we can see that most variances are from the first two dimensions. So the variance explained by each dimension drop off very quickly from 2 to 3, after 3, it drops very slow. So I believe that only 2 dimensions are enough to describe the whole database variances.

3) What do the dimensions seem to represent? How can you use this information?

Answer: The first dimensions includes a major portion of Fresh, the a small portion of Frozen production The second dimensions includes similar amount portion of Milk and Grocery, and a small portion of Detergents_paper.

This means only two PCA dimensions can express the most of variances. Based on the reduction by PCA, we can reduce the amount the computation and also remain most of the information.

4) For each vector in the ICA decomposition, write a sentence or two explaining what sort of object or property it corresponds to. What could these components be used for?

Answer:

- The first component of ICA primarily consists of Frozen and Delicatessen.
- The second component consists of Delicatessen, Milk, Grocery, Frozen
- The third component consists of Delicatessen, fresh.
- The fourth component consists of Delicatessen.
- · the fifth component consists of Fresh, Milk, Detergents paper
- the sixth component consists of Milk, Detergents paper, and Fresh

The ICA is just a method to decompose the multivariate data into independent non-Gaussian signals. In the clustering, it is important to have independent features

Clustering

In this section you will choose either K Means clustering or Gaussian Mixed Models clustering, which implements expectation-maximization. Then you will sample elements from the clusters to understand their significance.

Choose a Cluster Type

5) What are the advantages of using K Means clustering or Gaussian Mixture Models?

Answer: K means is a "simple", relative fast method to do "hard" assignments, which means one data point is definitely belong to only one group. K means is good for points are well separated. While Gaussian Mixture Models is a "soft" assignment, it is suitable for points are mixed together.

6) Below is some starter code to help you visualize some cluster data. The visualization is based on this.demo (http://scikit-learn.org/stable/auto_examples/cluster/plot_kmeans_digits.html) from the sklearn documentation.

```
In [5]: # Import clustering modules
    from sklearn.cluster import KMeans
    from sklearn.mixture import GMM
```

```
In [6]:
        # TODO: First we reduce the data to two dimensions using PCA to capture
        reduced data = PCA(n components = 2).fit transform(data)
        print reduced data[:10] # print upto 10 elements

         plt.show()
```

Clustering on the wholesale grocery dataset (PCA-reduced data)

Centroids are marked with white cross

7) What are the central objects in each cluster? Describe them as customers.

Answer: From the figure above, we can see that there are roughly three clusters. We can name the horizontal axis as variable 1, and vertical axis is variable 2. The lower right region (red) means the customers has more purchase about variable 1, and upper right region (blue) means the customers has more purchase about variable 2, and less purchase about variable 1. The other region (dark red) can be treated as outliers of the first two region, they has extreme high volume purchase of variable 1 or variable 2, or they has similar purchase amount of variable 1 and variable 2.

Conclusions

8) Which of these techniques did you feel gave you the most insight into the data?

Answer: PCA techniques enable us reduce the original 6 variables to only 2 independent variables. So we can views the variations in 2D plot, and also reduce the amount of calculation in later clustering.

In clustering, we use Gaussian Mixture Models to separate the customers into 3 different group. In each group, they has different purchase habits, (purchase some categories more than others). This information can enable the owner of wholesale distributor to make better business decision

9) How would you use that technique to help the company design new experiments?

Answer: Current, we have separated the customers into three groups. Further, we need gather more customers background information, to explore what factor cause these different customers purchase habit, such as location, average income, population, purchase purpose. Then we can use these information to identify the potential customer in each category to gather higher profit.

10) How would you use that data to help you predict future customer needs?

Answer: From the previous PCA analysis, we know that the variable 1 consists Fresh and Frozen, the variable 2 consists Milk, Grocery and Detergents_paper. So we know that the remaining category, Delicatessen, doesn't has a high demand in the market. So we can lower the storage of Delicatessen to reduce the cost. Also from the above figure, we know that the red region is more slender than blue region, that means the purchase amount of variable 1 is larger than of variable 2. In other words, in future, customer still needs more Fresh and Frozen products.
